

PetGuard AI

Computer Vision-Based Pet Restricted-Zone Monitoring

Tier 1 - Object Detection Application

PetGuard AI transforms ordinary camera footage into intelligent pet monitoring by detecting dogs and cats and determining when they enter user-defined restricted areas.

The Problem

"They Know When We're Not Watching." 

Happy
Pets
Better
Days 

Home cameras can record pets, but recording alone does not answer:

"Where is the pet, and is it somewhere it should not be?"

Real-world problem

Pet owners may want pets to stay away from:

Couch

Bed

Kitchen

Dining area

Other restricted areas

Reviewing camera footage manually is inefficient and provides little immediate context.

Computer-vision problem

PetGuard needs to solve two different questions:

Perception

What object is present, and where is it?

Spatial reasoning

Is that detected pet inside a restricted area?

Project objective

Develop a proof-of-concept system capable of:

Detecting a pet

Locating it

Evaluating its position

Generating a meaningful event

Key insight

Object detection tells us what and where.

PetGuard adds context to determine whether that location matters.

*Same Home.
Smarter Care.* 

System Architecture

From Pixels to Decisions 🐾

Any Camera.
Any Moment.
A Safer Home. ❤️

Live Camera

Video

Image

CAMERA / IMAGE / VIDEO

Capture pet activity from home cameras or uploaded media

FRAME INPUT

Extract frames from video or use image

PRETRAINED YOLO

OBJECT DETECTOR
Detect objects in the frame

DOG / CAT FILTER

Keep only dog and cat detections

CONFIDENCE THRESHOLD

Filter low-confidence detections

PET BOUNDING BOX

Get location (x, y, width, height)

SPATIAL ZONE REASONING

"Where is the pet?"
Check if the pet is inside a restricted area

TEMPORAL CONFIRMATION

"Is it persistent?"
Validate across multiple frames

SAFE

Pet is outside
restricted areas

VIOLATION

Pet is inside
a restricted area

EVENT LOG / ALERT

Save event, notify user, and provide visual evidence

Same Pets.

Images to Insights
for Happier Pets ❤️

dog 0.88

Computer Vision Technique

Object Detection

Baseline Model

YOLOv8n
with pretrained
COCO weights

Technology

Python • Ultralytics
PyTorch • OpenCV
Google Colab

Why YOLO?

YOLO is appropriate because PetGuard requires both:

Classification
Dog or cat?

+

Localization
Where is the pet?

For input frame I_t :

$$I_t \rightarrow \text{YOLO} \rightarrow \{B_i, C_i, S_i\}$$

where:

- B_i = bounding box
- C_i = predicted class
- S_i = confidence score

PetGuard retains detections where:

$$C_i \in \{\text{dog, cat}\}$$

Current Technical Proof

Test Image

YOLOv8n

1 Dog Detected

Confidence $\approx$ 87.9%

Bounding Box Extracted

Example Result (from Colab)

1 object detected:
- class: dog
- confidence: 0.879
- box: [102, 56, 628, 478]

Successfully detected the dog with $\sim$ 87.9% confidence! 🐾

Data Strategy

Real Data. Real Pets. Real Scenarios. 🐾

Diverse Data
Stronger Detection.
Safer Homes ❤️

Real-world scenes
Real pet behavior
Real impact ❤️

Planned Evaluation — ~200 Samples

Oxford-IIIT 100 images

- 50 cats + 50 dogs
- Controlled detection
- Well-known benchmark dataset for pet images

Example images from Oxford-IIIT

COCO 2017 50 images

- Realistic cat/dog scenes
- Challenging detection
- More complex backgrounds and real-world environments

Example images from COCO 2017

PetGuard (Custom) 50 images

- SAFE / VIOLATION scenarios
- Application-specific data
- Captured from home environments (or realistic simulations)

Example images from PetGuard dataset

Total: ~200 samples

A balanced mix of benchmark and real-world data to evaluate both detection and restricted-zone reasoning.

Same Data.

How PetGuard Reasons

Detection $\neq$ Understanding

It's not just
what they are,
but where they are.

Same pet.
Different story.
Different logic.
Smarter decisions.

1 YOLO Detection

YOLO detects pets and returns a bounding box.

$$B = (x_1, y_1, x_2, y_2)$$

B = bounding box
 C = predicted class
 S = confidence score

2 Bottom-Center Point

Instead of the center of the box, we use the bottom-center point to represent the pet's location on the ground.

Bottom-center point

$$P = \left(\frac{x_1 + x_2}{2}, y_2 \right)$$

Closer to where
the pet touches
the ground!

3 Restricted Zone (Polygon)

Define a restricted zone $Z = \{p_1, p_2, \dots, p_n\}$ as a polygon. PetGuard checks if the pet's point is inside the zone.

$$\text{Violation} = \begin{cases} 1 & P \in Z \\ 0 & P \notin Z \end{cases}$$

Restricted Zone (Z)

4 Furniture Scenario

For furniture (e.g., couch or bed), bottom-center may not be ideal. We compare two methods:

Method A: Point-in-Polygon

Check if the bottom-center point is inside the zone.

Method B: Bounding-Box Overlap

Check the overlap between the bounding box and the zone.

VS

Different scenarios need different reasoning.
We'll evaluate both methods to find what works best.

5 Temporal Reasoning

A single frame should not necessarily create an alert.
We check for persistent violations across multiple frames.

Not Confirmed

Do not confirm
(brief crossing or false detection)

Confirmed Violation

CONFIRMED VIOLATION
(persistent behavior)

Why Temporal Reasoning?

- ✓ Reduces false alerts from bounding-box jitter
- ✓ Handles momentary detection errors
- ✓ Avoids alerts from brief zone crossing
- ✓ More reliable and practical
- ✓ Makes PetGuard a decision system

Smarter
AI for
happier
homes.

Good
Pets
Brighter
Days.

From Detections to Decisions

Understand the scene. Respect the space. Keep pets safe.

Success Metrics

"Working" Must Be Measurable 🐾

A successful system is more than detecting pets — it's about making the right decisions, with low false alerts, and practical performance.

Measure what matters.
Build what works.
Happier homes. 🌱

GOOD
PETS
BRIGHTER
DAYS
♥

1 Pet Detection Recall

Of the pets actually present, how many did YOLO detect?

$$\text{Recall} = \frac{TP}{TP + FN}$$

Initial target
≥ 85%

Detected
(True Positive)

Missed
(False Negative)

2 Zone Decision Accuracy

How often did PetGuard correctly classify SAFE vs VIOLATION?

$$\text{Accuracy} = \frac{\text{Correct Zone Decisions}}{\text{Total Evaluated Cases}}$$

Initial target
≥ 90%

Correct decision

Correct decision

3 False Violation Rate

How often does PetGuard incorrectly alert when the pet is actually safe?

Target
≤ 10%

Should be SAFE,
but system incorrectly alerted
(False Positive)

4 Processing Performance

Measure inference time or FPS
(milliseconds/frame or frames per second).

Initial focus
Reliable inference
(over chasing real-time)

Current experiment (one run):

~ 196 ms per frame

Performance may vary by hardware and environment. We will optimize after the baseline system is working reliably.

Same Home.

Execution Plan + Risks

Build Small → Validate → Expand

Small Steps
Big Impact
Happier Homes

Plan.
Build.
Test.
Improve.
For a Happier
Tomorrow.

Risk Assessment

Anticipate challenges. Plan ahead. Keep the project on track.

Risk	Impact	Mitigation / Plan B
Pet not detected	High	Confidence tuning; controlled evaluation
Occlusion	Medium	Include occlusion test cases
Poor lighting	Medium	Evaluate separately; document limitation
Zone-boundary ambiguity	High	Compare point vs overlap methods
Bounding-box jitter	Medium	Temporal confirmation
Video too slow	Medium	Reduce resolution/frame sampling
Repeated alerts	Medium	Event cooldown/debouncing
Multiple pets	Medium	Evaluate each detected pet separately
Complex custom zones	Low	Use predefined polygon
Dataset limitations	Medium	Controlled evaluation set
Custom training becomes necessary	High	Remain with pretrained baseline for Tier 1
Final scope becomes too large	High	Protect minimum viable pipeline

Most Important Plan B

If things become difficult, we still have a clear, achievable final.

A solid plan
ensures a
successful final!
